

Introduction

The Hall's Sustainability Policy requires yearly reports on aspects relating to the three pillars of sustainability – economic, social and environmental - as a means of understanding impact and measuring improvements. The policy acknowledges that environmental attention should be focussed on the major environmental impact of the organisation, being its carbon footprint, which is addressed in this report.

Emissions

In considering the Hall's carbon emissions, this report uses the common framework assigning emission to scopes 1,2, or 3:

- **Scope 1:** carbon emissions arising directly from the activities of an organisation. For The Queen's Hall this comprises the gas burnt for heating.
- **Scope 2:** carbon emissions arising indirectly from activities carried out by others on our behalf. For The Queen's Hall this comprises the carbon emissions attached to our electricity usage. Water usage is arguably within scope 2, but the UK Government deems it to be scope 3.
- **Scope 3:** all other carbon emissions created in relation to the activities of the organisation such as by others in supplying products, and those generated by the use of the products of the organisation. For The Queen's Hall, water usage is placed in scope 3. Clearly, there are many other sources of emissions in this category which are outwith the control of The Queen's Hall, but which may be influenceable.

Offsets

The only offset claimed at present by The Queen's Hall is for electricity. The current supplier states that their contracted generation supply is all with renewable sources. This is a reasonable off-set to apply to the Hall's carbon footprint, but a truly renewable electricity supply will only happen when all sources of generation on the system are renewable, for which the present target date is mid 2040s.

Offsets generally are a fraught subject. Other offsets are available, particularly for gas supplies. These are of two types:

- Carbon removal – removing carbon from the atmosphere by projects such as atmospheric carbon capture, which is not yet commercially available, or tree planting, which takes a long time to sequester carbon, and is quite likely to re-release the carbon stored before the carbon it is offset against has decayed in the atmosphere.
- Carbon avoidance – largely involves investing in projects to reduce carbon emissions, often by paying for things to be done that should be done anyhow.

Commercial companies are interested in such offsets as it can be useful for signalling green intentions, but for The Queen's Hall the best project to invest in is reducing our own carbon footprint.

Control over emissions

The Queen's Hall has different levels of control over its various emissions:

- Scope 1 – high level of control where we can make decisions to directly affect the level of emissions.
- Scope 2 – considerable level of control over usage and source of supplies which generate emissions.
- Scope 3 – minimal level of control over emissions, but some capacity of choice and influence.

Quantified emissions

The methodology for producing the quantified emissions in the attached report sheet is as follows:

- For gas and electricity, the energy usage for the year in kWh comes from meter readings. For water, which is not metered, a usage per person attendance of 10 litres is assumed as an order of magnitude.
- Each usage figure is then multiplied by a factor issued yearly by the UK Government Department of Energy Security and Net Zero to yield a carbon dioxide equivalent (CO₂e) emission figure in kg.

The quantified emissions are given on the attached report sheet which shows:

- Absolute total emissions for 2025 of 71347 kgCO₂e
- Net total emissions after offsets of 51189 kgCO₂e

The specific emissions per audience person attendance are also given on the basis that reducing our emissions by reducing audience numbers is not compatible with economic sustainability. These are:

- Specific absolute emissions of 0.68 kgCO₂e per person attendance
- Specific net emissions of 0.49 kgCO₂e per person attendance.

Points of comparison

As two points of comparison:

- The total Queen's Hall emissions given above for the year 2025 are equivalent to those of 6 or 7 average domestic homes.
- In 2024, the average per person carbon footprint in the UK for the year was around 9.5 tonnes CO₂e, so the Hall's contribution to a visit to The Queen's Hall would be equivalent to around 2% of the average daily carbon footprint.

Changes from datum

An arbitrary datum year of 2022 has been set as the first nearly full year of normal operations after the Covid pandemic. In relation to that datum the net emissions have decreased to 80% of datum, and the specific carbon emissions per audience visit have declined to 68% of datum. This reduction is due both to increased attendance and the reduction in net total carbon emissions.

Other scope 3 emissions

Scope 3 emissions for The Queen's Hall, other than water, can be usefully grouped and considered as follows:

- **Emissions by artists and promoters in their activities in QH.** Our significant promoter partners are being asked about the state of their environmental policies and carbon footprint measurement, but it is acknowledged that QH has little influence over major promoters. For QH promotions, consideration is being given to how QH can persuade other parties to think about their environmental impact. An order of magnitude assessment (attached) has provided an estimated emissions per attendance for artist travel of 0.2kgCO₂e, which is about 40% of the direct emissions by the Hall per audience attendance.
- **Supplies to the bar business.** The major bar supplier is being asked about their environmental policies; in this area we do have more choice and hence somewhat greater influence.

- **Waste management.** The waste management contractor is being asked about their environmental policies; in this area also there is more choice and potentially greater influence.
- **Staff travel.** This is a very small component of the total emissions. Staff are encouraged to use public transport to get to work. The quantity of staff travel while at work is minimal.
- **Audience travel.** This is potentially a much larger component of total emissions, but one over which The Queen's Hall has little influence. Details of how to reach the Hall by public transport are posted on the website, but our capacity to persuade people into electric vehicles or active means of transport is strictly limited. An order of magnitude assessment for audience travel (attached) has provided an estimate of emissions per attendance of 2kgCO₂e, which is about 4 times the direct emission by the Hall per attendance.

Generally, it is submitted that The Queen's Hall's influence on scope 3 emissions is limited, but by continuing to ask the questions we would hope to persuade others to take action and to add to the general conversation and awareness of climate issues.

Future plans

The main activities in this area are guided by the 'Towards Net Zero' plan approved by the Board in December 2023 which was informed by extensive study work in conjunction with Harley Haddow Consultants.

Activities completed in 2025 relating to the carbon footprint are:

- A study by Harley Haddow Consultants on how to move the Hall heating to air source heat pumps by tackling the project in various independent zones. The study showed that this approach is viable though the electrical supply capacity needs further investigation.

Activities in the coming year which will impinge on our carbon footprint comprise:

- Progressing building insulation works around the WC area, funding permitting.
- Replacing the main stairway secondary glazing with vacuum glazed units to improve both heat and sound insulation and as a first step in the insulation of the east end wall.
- Investigate the limits on electrical supply to the Hall.
- Continue with funding applications for further work.

Targets

It is desirable to set targets for emissions reduction but while the Hall has capacity for conceiving and planning initiatives, and for seeking finance, the key requirement is external funding for implementation of what are largely capital projects of significant cost, which makes the timescales deeply uncertain.

The Hall therefore is pursuing a policy of progressing as far as possible in the definition of its various emissions reduction schemes, breaking them down into discrete projects where possible. This allows meaningful and targeted applications for funding to be made, with implementation as and when suitable funds are available.

The experience has been that funding is generally inadequate to the scale of the problem and is badly targeted even to the extent of actively encouraging bad practices.

Conclusion

In terms of actual carbon emissions, the situation has changed significantly from 2022, with actual emissions down by 12% and net emissions per attendance have decreased by 32% compared with the 2022 datum. The definition of the various initiatives for emissions reductions has moved forward significantly with a complete conceptual plan now in place. Funding is the key issue.

Emma Mortimore – CEO

Peter Cannell – Director of Estates

Presented to the Board at the March 2026 meeting
